ABSTRACT - The cost of assets is increasing day by day and the capital required to purchase an entire asset is very high. So purchasing it out of your savings is not possible. The easiest way to get the required funds is to apply for a loan. But taking a loan is a very time consuming process. The application has to go through a lot of stages and it's still not necessary that it will be approved. To decrease the approval time and to decrease the risk associated with the loan many loan prediction models were introduced. The aim of this project was to compare the various Loan Prediction Models and show which is the best one with the least amount of error and could be used by banks in the real world to predict if the loan should be approved or not taking the risk factor in mind. After comparing and analyzing the models, it was found that the prediction model based on Random Forest proved to be the most accurate and fitting of them all. This can be useful in reducing the time and manpower required to approve loans and filter out the perfect candidates for providing loans. Furthermore, feature importance analysis shows that important variables in determining the results of loan approvals include applicant income, credit history, loan amount, and loan term.By correctly identifying high-risk applicants, this loan prediction system can minimize the danger of default and ultimately increase the efficiency and profitability of lending institutions. It also has the potential to drastically reduce the human workload of loan officers. In order to improve predicted performance even further, future work will involve expanding the datasets used for model refinement, adding new features, and investigating cutting-edge methods like deep learning.

1. ***INTRODUCTION*** -

Loan Prediction is very helpful for employees of banks as well as for the applicant also. The aim of this Paper is to provide a quick, immediate and easy way to choose the deserving applicants. Dream housing Finance Company deals in all loans. They have presence across all urban, semi urban and rural areas. Customers first apply for a loan after that company or bank validates the customer eligibility for loan. Company or bank wants to automate the loan eligibility process (real time) based on customer details provided while filling the application

form. These details are Gender, Marital Status, Education, Number of Dependents, Income, Loan Amount, Credit History and other. This project has taken the data of previous customers of various banks to whom on a set of parameters loans were approved. So the machine learning model is trained on that record to get accurate results. Our main objective of this project is to predict the safety of loans. To predict loan safety, the SVM and Naïve bayes algorithm are used. First the data is cleaned so as to avoid the missing values in the data set. A Prediction Model uses data mining, statistics and probability to forecast an outcome. Every model has some variables known as predictors that are likely to influence future results. The data that was collected from various resources then a statistical model is made. The Prediction Model helps the banks by minimizing the risk associated with the loan approval system and helps the applicant by decreasing the time taken in the process. It is done by predicting if the loan can be given to that person on the basis of various parameters like credit score, income, age, marital status, gender, etc. The prediction model not only helps the applicant but also helps the bank by minimizing the risk and reducing the number of defaulters. In the present scenario, a loan needs to be approved manually by a representative of the bank which means that person will be responsible for whether the person is eligible for the loan or not and also calculating the risk associated with it. As it is done by a human it is a time consuming process and is susceptible to errors. If the loan is not repaid, then it accounts as a loss to the bank and banks earn most of their profits by the interest paid to them. If the banks lose too much money, then it will result in a banking crisis. This banking crisis affects the economy of the country. So it is very important that the loan should be approved with the least amount of error in risk calculation while taking up as little time as possible. So a loan prediction model is required that can predict quickly whether the loan can be passed or not with the least amount of risk possible.

Keywords: Machine Learning, Loan Approval Prediction , Algorithms, Random Forest, Logistic Regression, K Nearest Neighbor,

LITERATURE REVIEW

The author, Vaidya, Ashlesha [1] uses logistic regression as a machine learning tool in paper and shows how predictive approaches can be used in real world loan approval problems. His paper uses a statistical model (Logistic Regression) to predict whether the loan should be approved or not for a set of records of an applicant. Logistic regression can even work

with power terms and nonlinear effects. Some limitations of this model are that it requires independent variables for estimation and a large sample is required for parameter estimation.

A work by Amin, Rafik Khairul and Yuliant Sibaroni [2] was referenced which used a Decision tree algorithm called C4.5 to implement a predictive model. This algorithm creates a decision tree that generally gives a high accuracy in decision making problems. Dataset of 1000 cases is used in which 70% is approved and the rest is rejected. This paper shows C4.5 algorithm performance in recognizing the eligibility of the applicant to repay his/her loan. From the conducted tests, it is found that the highest precision value is 78.08% which was found using a data partition of 90:10. The greatest recall value is 96.4% and was reached with a data partition of 80:20. Partition of 80:20 is considered to be best since it has a high recall and the highest accuracy.

The research and work done by Arora, Nisha and Pankaj Deep Kaur [3] aimed at forecasting whether an applicant can be a loan defaulter or not. It uses Bolasso to select most relevant attributes based on their robustness and then applied to classification algorithms like Random Forest, SVM, Naive Bayes and KNearest Neighbours (KNN) to test how accurately they can predict the results. It is concluded that the Bolasso enabled Random Forest algorithm (BS-RF) provides the best results in credit risk evaluation and gives better accuracy by using optimised feature selection methods.

In paper authored by Yang, Baoan, et al. [4], the use of artificial neural networks in an early warning system for predicting loan risk is discussed wherein it covers the early warning signals for deteriorating financial situations. The ability of an applicant to repay the loan is determined to be the most relevant aspect in the financial analysis. The early warning system in this paper uses an artificial neural network that is utilizing the traditional early warning concepts. This system based on ANN proves to be a very effective decision tool and early warning system for banks and other commercial lending organizations.

The scope of using Genetic Algorithms in building prediction models was also discussed in the paper by Metawa Noura, M. Kabir Hassan and Mohamed Elhoseny [5]. This paper discusses a prediction model made using Genetic Algorithm which can facilitate banks in making lending decisions in case of decrease in lending supply. The main focus of the GA model is twofold: maximizing profit and minimizing errors in loan approval in case of dynamic lending decisions. Several factors like type of loan,

rating of creditor and expected loan loss are integrated to GA chromosomes and then validation is done. The result shows that GAMCC increases the profits of the bank by 3.9% to 8.1%. Yet another approach was used by Hassan, Amira Kamil Ibrahim and Ajith Abraham[6] wherein they used a German dataset and built a prediction model working basically on backpropagation and implemented with three different back propagation algorithms. They also used two different methods for two filtering functions for the attributes which resulted in DS2 giving highest accuracy using PLsFi filtering function.

MATERIALS & METHODS

The Dataset that has been used for this paper consists of 13 columns namely Loan, Gender, Married, Dependents, Education, Self_Employed, ApplicantIncome, CoapplicantIncome, LoanAmount, Loan_Amount_Term, Credit_History, Property_Area, Loan_Status. The Loan column gives a unique ID. Gender column mentions the gender of the applicant(Male/Female). Married column provides the marital status of the applicant(values will be Yes/No). Dependents column tells whether the applicant has any dependents or not. Education column tells whether the applicant is Graduated or not. Self_Employed column defines that the applicant is self-employed (i.e. Yes/ No). ApplicantIncome gives the applicant income. CoapplicantIncome column gives the co-applicant income. The LoanAmount column tells about loan amount (in thousands). Loan_Amount_Term column tells about terms of loan (in months). The Credit_History column tells about the credit history of an individual's repayment of their debts. Property_Area column tells about the area of property (i.e. Rural/Urban/Semi-urban). Loan_Status column tells whether the status of loan is approved or not (i.e. Y- Yes, N-No).

Hardware and Software Requirements:

Hardware requirements of the project include

- Laptop or Personal Computer

Software requirements include

- Internet browser (Chrome/Edge/Mozilla Firefox)
- Stable Internet connection
- Jupyter Notebook/ Google colab

2. *EXISTING SYSTEM*

Regarding loan default prediction, current systems assess borrowers' creditworthiness mostly by conventional statistical techniques and credit scoring models. These traditional methods include various heuristic-based approaches, logistic regression, and linear discriminant analysis; these are frequently included into credit scoring systems such as FICO scores.Banks, Housing Finance Companies and some NBFC deal in various types of loans like housing loan, personal loan, business loan etc in all over the part of countries. These companies have existence in Rural, Semi Urban and Urban areas. After applying for a loan by a customer , these companies validate the eligibility of customers to get the loan or not. This project provides a solution to automate this process by employing machine learning algorithms. So the customer will fill an online loan application form. This form consists of details like Sex, Marital Status, Qualification, Details of Dependents, Annual Income, Amount of Loan, Credit History of Applicant and others. These scores are determined by looking at things like length of credit history, new credit, quantities outstanding, payment history, and credit kinds that are employed. Credit ratings, while useful in certain situations, generally give a static picture of a borrower's creditworthiness and do not account for behavioral shifts that occur in real time. Heuristic principles and financial measures, such as loan-to-value and debt-to-income ratios, are also used in traditional loan evaluation.

3. PROPOSED SYSTEM

The paper will be comparing different prediction models and deduce their limitations as well as advantages. Since all the research papers used different sets of data to infer the accuracy and for cross validation of data, the authors have used the same data for all the models which will give a clearer view on their performance and lead to a better comparison of the same. On the basis of the results, a modified prediction model will be created to ensure maximum accuracy and performance.

4. METHODOLOGY

Data Collection :

The first phase of the project involves data from trusted sources such as kaggle.The data set collected should have desired data columns and be able provide better results and the size should be sufficient enough.

Data Preprocessing :

The Data collected won’t be in a state that can be used for training purposes hence, the data should undergo the step of preprocessing in

which common problems are eradicated such as missing values , improper spelling in data or incorrectness in data etc. Various python libraries specialized for data analysis can be utilized for this purpose such as Numpy, Pandas.This step is crucial for the project as these may cause inefficiency if they are fed directly to the model.

EDA :

EDA stands for Exploratory Data Analysis in which the entire acquired data is analyzed for its relation within the data. Any outliers or deviation of data can be inferred at this point and also this helps to gain the significance of each data column. The common libraries utilized for this step include Matplotlib and Seaborn. Both of these are visualization tools commonly used in the project. Through EDA, we concluded that several attributes of users such as phone number, user id etc. are redundant and thus they are dropped. Heatmaps are extensively used to know the correlation between various attributes.

Model Training:

The vectorized text data is used to train a convolutional neural network model . During training, the model adjusts its internal parameters iteratively to minimize a defined loss function. Dropout layers are included to prevent overfitting, ensuring the model generalizes well to unseen data. The model is trained using a portion of the data, while performance is monitored using a separate validation set.

Model Evaluation:

Once training is complete, the model's performance is evaluated using a separate test dataset. Performance metrics such as accuracy, precision, and recall are calculated to assess the model's effectiveness in classifying legal descriptions.

ALGORITHM USED

Linear Regression- It is a statistical method used to determine the relationship between a dependent variable and one or independent variables. Linear regression aims to find the Best fitting straight line; it describes the relationship between the predictor values and target values.

Random Forest-It is an ensemble learning method that combines different decision trees to improve the predicting accuracy and decrease overfitting. It uses both classification and regression.

IMPLEMENTATION & RESULT

4.1 Importing Libraries and Dataset

Firstly we have to import libraries :

- Pandas – Python library used to load the Data Frame
- Matplotlib – Python library visualize the data features i.e. barplot
- Seaborn – Python library to see the correlation between features using heatmap

```
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
import seaborn as sns

data = pd.read_csv("LoanApprovalPrediction.csv")
```

```
C:\Users\admin\AppData\Local\Temp\ipykernel_12880\3117320796.py:1: DeprecationWarning:
Pyarrow will become a required dependency of pandas in the next major release of pandas (pandas 3.0),
(to allow more performant data types, such as the Arrow string type, and better interoperability with other libr
but was not found to be installed on your system.
If this would cause problems for you,
please provide us feedback at https://github.com/pandas-dev/pandas/issues/54466

  import pandas as pd
```

After importing our dataset, let's view it by using a simple method,

```
data.head(5)
```

	Loan_ID	Gender	Married	Dependents	Education	Self_Employed	ApplicantIncome	CoapplicantIncome	Lo
0	LP001002	Male	No	0.0	Graduate	No	5849	0.0	
1	LP001003	Male	Yes	1.0	Graduate	No	4583	1508.0	
2	LP001005	Male	Yes	0.0	Graduate	Yes	3000	0.0	
3	LP001006	Male	Yes	0.0	Not Graduate	No	2583	2358.0	
4	LP001008	Male	No	0.0	Graduate	No	6000	0.0	

Loan_Amount_Term	Credit_History	Property_Area	Loan_Status
360.0	1.0	Urban	Y
360.0	1.0	Rural	N
360.0	1.0	Urban	Y
360.0	1.0	Urban	Y
360.0	1.0	Urban	Y

4.2 Data Preprocessing and Visualization

In this step, we get the number of columns of object data type.

```
obj = (data.dtypes == 'object')
print("Categorical variables:",len(list(obj[obj].index)))
```

```
Categorical variables: 7
```

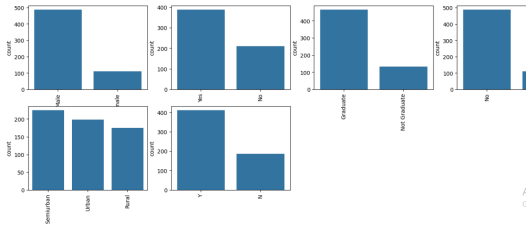
Then, as Loan_ID is completely unique and it is not correlated with any of the other columns, we drop it using the drop() function.

```
# Dropping Loan_ID column
data.drop(['Loan_ID'],axis=1,inplace=True)
```

4.3 Visualizing all the unique values in columns using barplot will simply show which value is dominating as per our dataset.

```
obj = (data.dtypes == 'object')
object_cols = list(obj[obj].index)
plt.figure(figsize=(18,36))
index = 1

for col in object_cols:
    y = data[col].value_counts()
    plt.subplot(11,4,index)
    plt.xticks(rotation=90)
    sns.barplot(x=list(y.index), y=y)
    index +=1
```



As we see, As all the categorical values are binary so we can use Label Encoder for all such columns and the values will change into **int** datatype.

```
# Import label encoder
from sklearn import preprocessing

# label_encoder object knows how
# to understand word labels.
label_encoder = preprocessing.LabelEncoder()
obj = (data.dtypes == 'object')
for col in list(obj[obj].index):
    data[col] = label_encoder.fit_transform(data[col])
```

Again we check for the object datatype columns finding out if there is still any left.

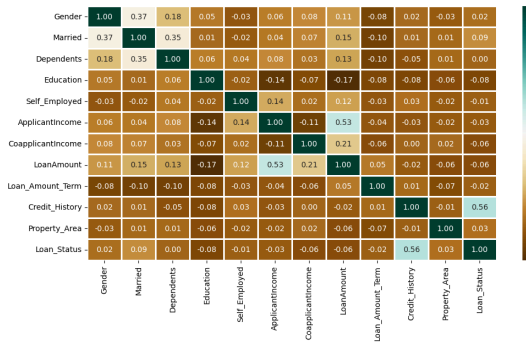
```
# To find the number of columns with
# datatype==object
obj = (data.dtypes == 'object')
print("Categorical variables:",len(list(obj[obj].index)))
```

```
Categorical variables: 0
```

```
plt.figure(figsize=(12,6))

sns.heatmap(data.corr(),cmap='BrBG',fmt='.2f',
            linewidths=2,annot=True)
```

```
<Axes: >
```

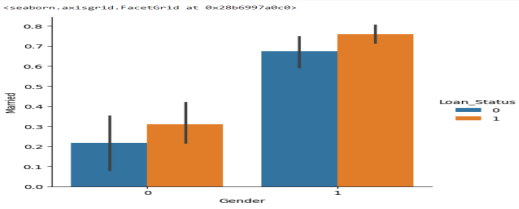


The above heatmap is showing the correlation between Loan Amount and ApplicantIncome. It also shows that Credit_History has a high impact on Loan_Status.

Using Catplot, we visualize the plot for the Gender, and Marital Status of the applicant.

```
sns.catplot(x="Gender", y="Married",
            hue="Loan_Status",
            kind="bar",
            data=data)
```

```
<seaborn.axisgrid.FacetGrid at 0x28b6997a8c0>
```



4.4 Model Training & Evaluation

As this is a classification problem, we will be using the models like

- KNeighborsClassifiers
- RandomForestClassifiers
- Support Vector Classifiers (SVC)
- Logistics Regression

We will use the accuracy score function from scikit-learn library to predict the accuracy

```
from sklearn.neighbors import KNeighborsClassifier
from sklearn.ensemble import RandomForestClassifier
from sklearn.svm import SVC
from sklearn.linear_model import LogisticRegression

from sklearn import metrics

knn = KNeighborsClassifier(n_neighbors=3)
rfc = RandomForestClassifier(n_estimators = 7,
                             criterion = 'entropy',
                             random_state =7)
svc = SVC()
lc = LogisticRegression()

# making predictions on the training set
for clf in (rfc, knn, svc,lc):
    clf.fit(X_train, Y_train)
    Y_pred = clf.predict(X_train)
    print("Accuracy score of ",
          clf.__class__.__name__,
          "=",100*metrics.accuracy_score(Y_train,
                                         Y_pred))
```

```
Accuracy score of  RandomForestClassifier = 98.04469273743017
Accuracy score of  KNeighborsClassifier = 78.49162011173185
Accuracy score of  SVC = 68.71508379888269
Accuracy score of  LogisticRegression = 79.88826815642457
```

Prediction of test set

```
# making predictions on the testing set
for clf in (rfc, knn, svc,lc):
    clf.fit(X_train, Y_train)
    Y_pred = clf.predict(X_test)
    print("Accuracy score of ",
          clf.__class__.__name__,"=",
          100*metrics.accuracy_score(Y_test,
                                     Y_pred))
```

```
Accuracy score of  RandomForestClassifier = 82.5
Accuracy score of  KNeighborsClassifier = 63.74999999999999
Accuracy score of  SVC = 69.16666666666667
Accuracy score of  LogisticRegression = 80.0
```

CONCLUSION

The implementation of the system to analyze the allocation of loan to the individual based on their details of the past and current details with the help of machine learning algorithm provides insights to the banking institutes to set the basic criteria for allocation of loan to them. The accuracy of the algorithm is useful for setting the criteria for each of the predictions for individuals. The RandomForestClassifier algorithm provides the overall highest accuracy with the dataset compared to the other algorithms implemented.
Each algorithm has its own merits and demerits. The algorithm with highest accuracy is used.

FUTURE ENHANCEMENTS

The system can be improvised with the implementation of the updated algorithms with the help of real time data updation and training the model in a periodic way can improvise the accuracy. Providing a dataset which consists of present criteria for the loan prediction will improvise the algorithm's accuracy and the implementation of the system will be made efficient.
